# **Bridge Amplifiers:**

- The output signal from a resistance bridge is usually very small in comparison to the reference signal, and it has to be amplified to increase its voltage level to a useful value (e.g., for use in system monitoring, data logging, or control).
- This is typically an instrumentation amplifier, which is essentially a sophisticated differential amplifier.
- The bridge amplifier is modeled as a simple gain  $K_a$ , which multiplies the bridge output.

### Half-Bridge Circuits:

- A half bridge has only two arms.
- Output is tapped from the mid-point of these two arms.
- The ends of the two arms are excited by two voltages, one of which is positive and the other negative.
- Initially, the two arms have equal resistances so that nominally the bridge output is zero.
- One of the arms has the active element. Its change in resistance results in a nonzero output voltage.
- It is noted that the half-bridge circuit is somewhat similar to a potentiometer circuit (a voltage divider).

The two bridge arms have resistances  $R_1$  and  $R_2$ , and the output amplifier uses a feedback resistance  $R_f$ .

To get the output equation, we use the two basic facts for an unsaturated opamp;

- 1. The voltages at the two input leads are equal (due to high gain), and
- 2. The current in either lead is zero (due to high input impedance).

Hence, voltage at node A is zero and the current balance equation at node A is given by:

# **Impedance Bridges:**

- AC Bridge
- Contains four impedances:  $Z_1, Z_2, Z_3$  and  $Z_4$

**Owen Bridge:** 

# Wien Bridge Oscillator:

## **Response parameters for time-domain specification of performance:**

#### **Delay Time:**

This is usually defined as the time taken to reach 50% of the steady-state value for the first time. This parameter is also a measure of speed of response.

#### **Peak Time**

The time at the first peak of the device response is the peak time. This parameter also represents the speed of response of the device.

#### **Settling Time**

This is the time taken for the device response to settle down within a certain percentage (typically+2%) of the steady-state value. This parameter is related to the degree of damping present in the device as well as the degree of stability.

#### **Percentage Overshoot**

This is defined as,  $PO = 100(M_P - 1)\%$ , using the normalized-to-unity step response curve, where  $M_P$  is the peak value. Percentage overshoot (PO) is a measure of damping or relative stability in the device.

#### Simple Oscillator Model:

#### TABLE 3.1

Time-Domain Performance Parameters Using the Simple Oscillator Model

Performance Parameter	Expression
Rise Time	$T_{\rm r} = \frac{\pi - \phi}{\omega_{\rm d}}$ with $\cos \phi = \zeta$
Peak Time	$T_{ m p}=rac{m{\pi}}{m{\omega}_{ m d}}$
Peak Value	$M_{ m p} = 1 - { m e}^{-\pi  \zeta/\sqrt{1-\zeta^2}}$
Percentage Overshoot (PO)	$PO = 100 e^{-\pi \zeta / \sqrt{1-\zeta^2}}$
Time Constant	$ au = rac{1}{\zeta \omega_{ m n}}$
Settling Time (2%)	$T_{\rm s} = -rac{\ln\left[0.02\sqrt{1-\zeta^2} ight]}{\zeta\omega_{ m n}} \approx 4 au = rac{4}{\zeta\omega_{ m n}}$

An automobile weighs 1000 kg. The equivalent stiffness at each wheel, including the suspension system, is approximately  $60.0 \times 10^3$  N/m. If the suspension is designed for a percentage overshoot of 1%, estimate the damping constant that is needed at each wheel.

#### Solution:

#### **Active Sensors:**

- External power is required to operate active sensors/transducers, and they do not depend on their own power conversion characteristics for operation.
- A good example for an active device is a resistive transducer, such as a potentiometer, which depends on its power dissipation through a resistor to generate the output signal.
- Note that an active transducer requires a separate power source (power supply) for operation,

#### **Passive transducer:**

- Draws its power from a measured signal (measurand).
- Since passive transducers derive their energy almost entirely from the measurand, they generally tend to distort (or load) the measured signal to a greater extent than an active transducer would. Precautions can be taken to reduce such loading effects.
- On the other hand, passive transducers are generally simple in design, more reliable, and less costly.
- For example, a piezoelectric charge generation is a passive process. But, a charge amplifier, which uses an auxiliary power source, would be needed by a piezoelectric device in order to condition the generated charge.
