- Library Sorting

Sorting by Recursion (Review)

Use Divide and Conquer to sort recursively.

1. Split the array into two roughly equal pieces.
2. Recursively sort each half.
 - This works because each piece is *smaller*.
3. Join the two pieces together to make one sorted array.

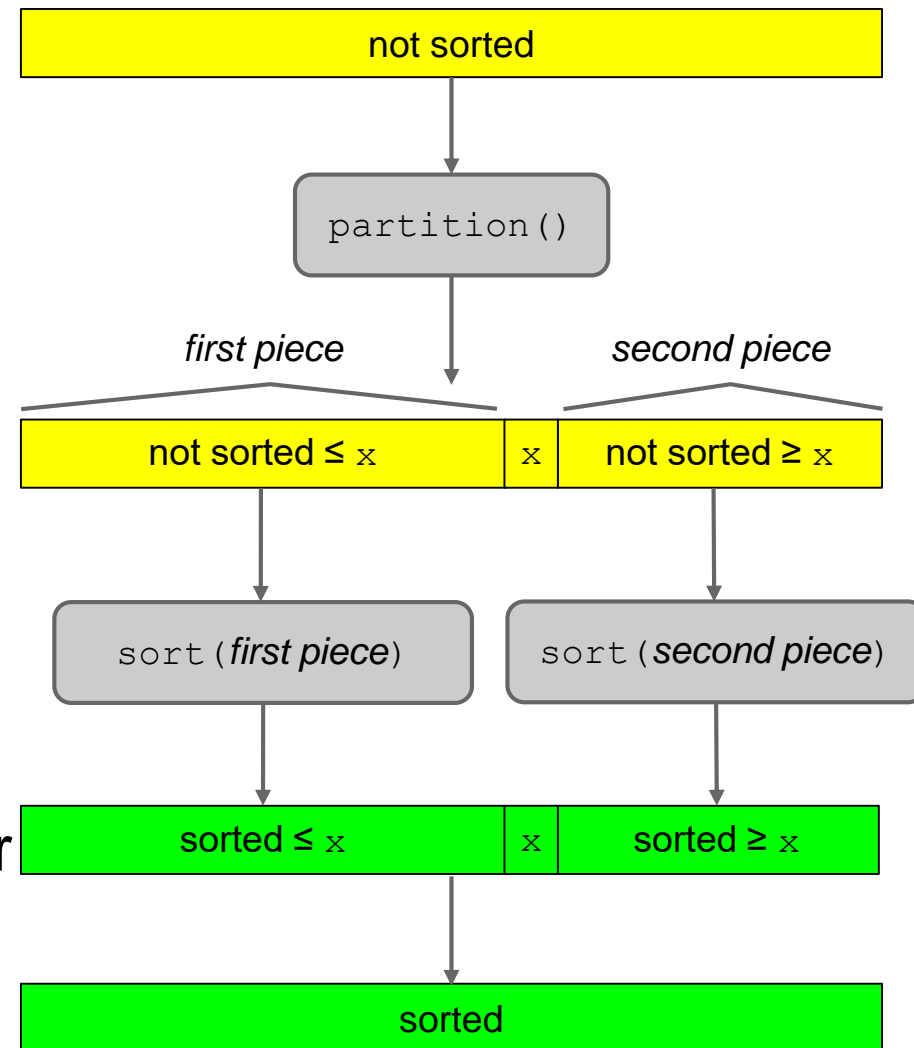

Two famous sorts behave this way: *mergesort* and *quicksort*.

Quick Sort

Strategy: Divide and Conquer

1. Split the array into two roughly equal pieces.
 - partition by a *pivot* element, x
2. Recursively sort each half.
 - two recursive calls to `sort()`
 - assume smaller cases are sorted correctly
3. Join the two pieces together to make one sorted array.
 - trivial

Example

pivot

15	-4	18	22	0	5	49	42	25	23	-8	-3	6
----	----	----	----	---	---	----	----	----	----	----	----	---

Partition

≤ 15

≥ 15

-4	0	5	-8	-3	6
----	---	---	----	----	---

15

18	22	49	42	25	23
----	----	----	----	----	----

Recursively Sort

Recursively Sort

-8	-4	-3	0	5	6
----	----	----	---	---	---

15

18	22	23	25	42	49
----	----	----	----	----	----

≤ 15

≥ 15

Quick Sort Code

```
// Post:  arr[first..last] are sorted  
void quickSort(int arr[], int first, int last) {
```

- **Base case**

- return if fewer than 2 elements

- **Split array into two roughly equal pieces**

- partition around a pivot element
- pivot element in correct position → mid

- **Recursively sort each piece**

```
}
```

Quick Sort Code

```
// Post:  arr[first..last] are sorted
void quickSort(int arr[], int first, int last) {
    // Base case
    if (last <= first) return;

    // Split array
    int mid = partition(arr, first, last);

    // Recursively sort
    quickSort(arr, first, mid-1);
    quickSort(arr, mid+1, last);
}
```

Partition

Q. How long does it take to partition N elements?

Strategy: Compare pivot with each element

- If less than pivot, put on left piece
- If greater than pivot, put on right piece

How to develop each piece?

There are many implementations of partition.

- To make our own, visualize a partially partitioned array:

Need two indices:

- index to scan through the array of indices (`sweep`)
 - marks end of the second piece
- index to mark end of the first piece (`mid`)

Q. What's the last step?

- Place the pivot
- swap with `arr[mid]`

Algorithmic Strategy:

- if `arr[sweep] > pivot` then
 - add it to the second piece
 - (do nothing)
- if `arr[sweep] < pivot` then
 - add it to the first piece
 - swap with `arr[mid+1]`
 - `mid++`

Running Time Analysis

What's the worst case running time?

- depends on the partition
- if it's an even split, then $O(N \log N)$ like Merge Sort.
- Q. What if it's a uneven split on every partition?
- $O(N^2)$ like Insertion Sort

It turns out that Quick Sort works well over all possible permutations of arrays

- $O(N \log N)$ in the average case
- Most implementations pick a random pivot

Generic Sorts

There is a function `qsort()` in `<stdlib.h>`

Parameters:

- a comparator function
- an arbitrary array of data

Remember that arrays are specified by:

- base address
- **type**
- number of elements

C++ uses the *template* construct to make generic typing easier

Generics promote code reuse by generalizing algorithms over different **types**

Sorting Algorithms: Summary

- For great sound effects:

<https://youtu.be/92BfuxHn2XE>

Selection Sort - 31 comparisons, 61 array accesses, 60 ms delay
